Frequently Asked Questions

What is the main difference between a virion and a virus?

A virion is the complete, intact virus particle that is capable of infecting a host cell, while a virus refers to the genetic material and proteins that make up the virion.

What are the two main types of viral genomes?

The two main types of viral genomes are DNA and RNA, which can be either single-stranded or double-stranded.

What is the function of the viral capsid?

The viral capsid is a protein shell that surrounds the viral genome and protects it from the environment, also playing a role in the attachment and penetration of the host cell.

What is the difference between a lysogenic and lytic cycle?

A lysogenic cycle is a type of viral replication where the viral genome is integrated into the host genome and remains dormant, while a lytic cycle is a type of viral replication where the virus takes over the host cell's machinery to produce new virions, eventually leading to the death of the host cell.

How do retroviruses replicate?

Retroviruses replicate by converting their RNA genome into DNA using the enzyme reverse transcriptase, which is then integrated into the host genome.
