Frequently Asked Questions

What is the main difference between mitosis and meiosis in Campbell Biology?

The main difference between mitosis and meiosis is that mitosis results in two daughter cells that are genetically identical to the parent cell, while meiosis results in four daughter cells that are genetically unique due to crossing over and independent assortment.

How do cells regulate gene expression according to Campbell Biology?

Cells regulate gene expression through various mechanisms, including transcriptional control, post-transcriptional control, and translational control, which involve the interaction of transcription factors, RNA interference, and microRNAs to fine-tune gene expression.

What is the role of ATP in cellular respiration in Campbell Biology?

ATP (adenosine triphosphate) is the primary energy currency of the cell, and its role in cellular respiration is to store and release energy as needed, with the energy from glucose being converted into ATP through the processes of glycolysis, pyruvate oxidation, the citric acid cycle, and oxidative phosphorylation.

What are the stages of photosynthesis in Campbell Biology?

The stages of photosynthesis are the light-dependent reactions and the light-independent reactions (Calvin cycle), which work together to convert light energy from the sun into chemical energy in the form of glucose.

How do prokaryotic cells differ from eukaryotic cells according to Campbell Biology?

Prokaryotic cells differ from eukaryotic cells in that they lack a true nucleus, have a single circular chromosome, and lack membrane-bound organelles, whereas eukaryotic cells have a true nucleus, multiple linear chromosomes, and various membrane-bound organelles.

What is the purpose of the electron transport chain in Campbell Biology?

The electron transport chain is a series of protein complexes located in the mitochondrial inner membrane that generates a proton gradient, which is used to produce ATP through the process of chemiosmosis, thus playing a crucial role in the production of energy for the cell.

How does natural selection lead to adaptation in populations according to Campbell Biology?

Natural selection leads to adaptation in populations by favoring individuals with traits that are better suited to their environment, thus increasing their chances of survival and reproduction, and passing

those traits on to their offspring, which over time can lead to the evolution of new species.
